ABSTRACT
The burden of cancer is still increasing worldwide despite advances for diagnosis and treatment. Epidemiological studies have shown that many cancers may be avoidable. It is widely held that 80–90% of human cancers may be attributable to environmental and lifestyle factors such as tobacco, alcohol and dietary habits. It was estimated that in the year 2000, worldwide over 10 million new cases of cancer occurred (approximately 5.3 million men and 4.7 million women) and over 6 million people died from cancers.
This study aims to evaluate the presence of langerhans cells in various histological stages of OSMF using CD1a antibody, which has been suggested as the most reliable marker of langerhans cells differentiation & to determine whether alterations in the number of LCs impairs oral mucosal immunologic protection against mutagens such as areca nut (betel quid), tobacco constituents, which might play a role in oral epithelial dysplasia& oral squamous cell carcinoma.

Keywords : OSMF, CD1a,Langerhans cells, Immunohistochemical study

INTRODUCTION

Fibrous collagen is synthesized as a protein (procollagen) in a manner similar to protein of other cells. As suggested by various researchers pathogenesis of OSMF shows a definite increase of collagen which is a protein, in the areas affected by this condition locally. Exuberant collagen formed being the primary tissue component in OSMF has been compared with an excessive scar tissue formation in healing wounds because of constant irritation. Fibroblasts are widely recognized as a critical cell type involved in wound healing and tissue repair. Fibrogenic cytokines are secreted by activated macrophages or T lymphocytes are very important in the development of fibrotic disorders. Less generally appreciated is the notion that the transformation of fibroblast to myofibroblasts is a key, perhaps essential, event for the cells to perform these functions.

The oral mucosa that is continuously exposed to a variety of injurious agents with antigenic properties, such as tobacco & tobacco smoke. **Langerhans cells (LCs)** may well represent a "**first-line**" of sensitization of the immune system, leading to clearance of antigen or to pathological phenomena as their absence can lead to disease initiation or progression. Recent studies have highlighted mucosal LCs as important arbiters of mucosal immune responses. According to Daniels et al., alterations in the number of Langerhans cells in tobacco-associated lesions is a result of changes caused by tobacco & is one factor in the long term pathogenesis of oral carcinoma.

LCs are bone marrow-derived epidermal dendritic cells & are present in the epithelium of the skin & mucosa, including the oral cavity. They are readily identified in the epithelium by special stains or with the help of immunohistochemical markers (CD1a) in addition to the presence of dendritic processes & suprabasal position.

LCs perform important immunologic functions by participating in cutaneous & mucosal immune reactions that can have both local & systemic effects. LCs have a specialized role in the presentation of non-peptide antigens to T cells, & this function is mediated by the antigen presenting molecule CD1a, which is highly expressed by these cells.

AIMS AND OBJECTIVES

Aims:

1) To assess the severity of the disease by clinical and functional staging.
2) To correlate clinical and functional staging with histopathological staging.
3)To study the expression of CD1a in Oral Submucous Fibrosis patients &to assess the number and distribution of Langerhans cells in OSF tissue & compare with normal control.
4) To evaluate possible correlation of Langerhans cells using CD1a marker in Oral Submucous fibrosis and its other histological grades.

Objectives:

1) To help assess the prognosis of the disease.
2) In future, to aid in planning the treatment of OSMF.

Through the present study, it was intended to establish a possible correlation between habits, clinical features, histopathological grading of oral submucous fibrosis & its correlation with langerhans cells expression using CD1a marker.

MATERIALS AND METHODS

This study was carried out in the Department of Oral Pathology and microbiology in Dr. D. Y. Patil Dental College and Hospital, Nerul, Navi Mumbai.

MATERIAL USED IN THE STUDY:

1. Mouth Mirror, probe and tweezer.
2. Gloves.
3. BP Blade 15 no.
4. Tissue holding Forceps
5. Sterile Cotton
6. Sterile bulb for sample collection
7. 10% Formalin.
8. Grossing Table
9. Measuring Scale
10. Leukhardts 'L' Block
11. Paraffin Wax
12. Coplin Jars
13. 60%, 75%, 90%,100% Graded Ethanol
14. Acetone (Pure)
15. Xylene
16. Harris's Haematoxylin
17. Acid Alcohol.
18. Eosin
19. Blotting Paper
20. Glass slide.
21. Cover slip
22. Mounting Media. (DPX – Disterenedibutylphthalate xylol)
23. Semi-automatic Microtome (Leica, Germany)
24. Hot Plate.
25. Water Bath
26. Light Binocular Microscope.
27. Poly L lysine coated slides (Biogenex, USA).
28. Di sodium hydrogen phosphate – anhydrous (Purified)
29. Sodium Di hydrogen phosphate
30. Distilled Water.
31. Conical Flask.
32. Glass Stirrer
33. Glass Beaker.
34. pH meter.
35. Weighing Scale
36. Incubator – Wooden Make
37. Antigen-retrival Machine (EZRetriver- Biogenex, CA, USA).
38. Anti CD1a Anitbody (Biogenex, CA, USA) – Prediluted.
39. Secondary Anitbody kit (Biogenex, CA, USA)

Article Received: Revised: Accepted:

Fig 1: Clinical Examination Tools

Fig 2: Vernier Calliper

METHODOLOGY:

Steps involved in carrying out the study:

I. Sample selection.
II. Sample Collection.
A. Blood Sample collection.
B. Tissue sample collection.
III. Haematoxylin & eosin staining of biopsy tissue sample.
IV. Staining of biopsy tissue sample using CD1a via immunohistochemistry.
V. Paraffin embedded sections of biopsies of the study groups will be stained by H&E.
VI. The serial sections of the same will be stained by immunohistochemical marker using CD1a and observed under microscope.
VII. Qualitative and quantitative analysis of langerhans cells will be done.
VIII. Two hot spots will be viewed under low magnification (4x).
IX. Images of these hot spots will be captured under higher magnification (40x).
X. The number of LCs will be counted manually from the images captured.
XI. The average figures which were obtained in the counted hot spot fields were considered as LC density.
XII. All counts were performed by a single investigator to eliminate an inter-observer variation.
XIII. Correlation between habits, clinical features, histopathological grading of oral submucous fibrosis & its correlation with langerhans cells expression.

I.SAMPLE SELECTION.

Sample size:

The total number of the samples in the present study comprised of 40 patients.

The participants were categorized into the following subdivision,

1) 30 cases of OSMF
2) 10 cases were selected as control group

Methods and criteria used for sample selection

Inclusion criteria – The control patients were selected according to criteria such as, clinically healthy persons without the history of any oral habits like tobacco, pan, and alcohol, consumption, smoking and normal appearing oral mucosa.

Exclusion criteria – Antibiotics in the course of the previous month , bleeding risk (anticoagulant therapy) chemotherapy and / or immunosuppressant therapy, endocarditis risk, patients radiated in the head and neck region, infection risk (e.g. ,HIV , HBV ,HCV ,TB) .

Patients with clinically evident palpable bands of OSMF comprised the cases. Specially prepared case sheets (Annexure 1) were used to record data of patients. At first examination each patient was interviewed to obtain case history with special reference to possible etiological factors and detail clinical examination. Routine haematological examination was performed. Clinical photographs were taken. Each patient was subjected to biopsy procedure. Proper medication and postoperative instructions were given to the patients.

All the samples were collected from the Out Patient Department of Dr.D.Y.Patil Dental College and Hospital. Nerul, Navi Mumbai, Maharashtra. All the study participants were given clear explanations about the objective of the study and a written informed consent was taken after a standard questionnaire interview was performed to obtain the history. It was ensured that adequately sterilized instruments were used for oral examination and sample collection to prevent cross-infection.

For clinical grading of OSMF criteria of Lai DR (1995) was taken in to consideration in present study. Mouth opening of each patient was measured using a Vernier Calliper

Group A: Mouth opening greater than 35mm
Group B: Mouth opening between 30- 35 mm
Group C: Mouth opening between 20- 30 mm
Group D: mouth opening less than 20 mm.

II. SAMPLE COLLECTION

A. Tissue sample collection.

Tissue biopsy samples were obtained from the affected site in case of OSMF and from normal buccal mucosa from control subject who were undergoing surgical procedure.

Processing of the tissue biopsy

Tissue biopsy samples were obtained. The tissues were processed and later stained by the routine Haematoxylin and eosin procedure and slides was interpreted for the confirmation of the diagnosis.

Specimen Accessioning

Tissue specimens after the surgical pathology laboratory had a request form that listed the patient information and history along with a description of the site of origin. The specimens were accessioned by giving them a number to identify each specimen for each patient.

Gross specimen examination

Gross examination consisted of describing the specimen and placing all or parts of it into a small cassette which holds the tissue (fig 14). Than all the tissues were processed in automated tissue processing machine (YORCO) for paraffin embedding technique as follows:

Fixation

The purpose of fixation was to preserve tissues permanently in as life-like as state as possible. Fixation was carried out immediately after removal of the tissues. 10% formalin was used for fixation.

Tissue Processing

Once the tissue was fixed, it was processed into a form in which it can be made into thin microscopic sections.

1. **Dehydration**: Wet fixed tissues (in aqueous solutions) cannot be directly infiltrated with paraffin. First, the water from the tissues was removed by dehydration. This was done with a series of alcohols, 70% to 95% to 100%.
2. **Clearing**: It consists of removal of the de-hydrant with a substance that is miscible with the embedding medium (paraffin). The clearing agent we used was xylene which is:

- highly volatile flammable
- tissues are rendered transparent by xylene
- prolonged treatment makes tissue brittle
- Tissue block of less than 5 mm thickness will be cleared in an hour.

3. **Infiltration**: The tissue was infiltrated with the embedding agent paraffin.
4. **Embedding**: Tissues that came off the tissue processor were manually put into the blocks by picking the tissues out of the cassette and then tissues was aligned, or oriented, properly in the block of paraffin.
5. **Paraffin section cutting**: Once the tissues were embedded, they were cut into sections that can be placed on a slide.

a.Semi automated microtome was used to cut 5µ thick sections.

b. Water bath was used to unfold the tissue section.

- The thermostatically controlled type was used.
- The temperature of water was maintained 10degree c below the melting point of paraffin wax.
- Allowing the section tooflatten out with greater ease.

6. **Slides**: once the tissue sections were unfolded they were taken on slide.

- 76 by 25 mm slides in dimension and thickness 1 to 1.2 mm were used.
- "Ground & polished edge" slides were used to reduce dangers of finger cut.

7. **Section adhesives**: Protein adhesives egg albumin was used as adhesives.
8. Slides were placed in slide stand to dry.

III.HAEMATOXYLIN & EOSIN STAINING OF THE TISSUE SAMPLE.

The cut sections were then subjected to Haematoxylin & Eosin staining.

The stained slides were interpreted for the conformation of the diagnosis.

Staining Protocol: For histopathological grading of fibrosis criteria given by **Ranganathan K** in 2007 was taken into consideration in present study.The histological diagnosis of OSMF was established if the following findings were observed:

- Epithelium: Type of keratinization–para / orthokeratosis
- Thickness–atrophic / hyperplastic
- Dysplasia–mild / moderate / severe
- Connective tissue: Type of fibrous tissue–loose / dense
- Hyalinization–partial / complete
- Inflammatory cells: Acute / Chronic; focal / diffuse;

• juxtaepithelial / perivascular

Staining protocol

1. Deparaffinize the slide:

a.Slides are placed on hotplate.

b. Dip in xylene: I, II, III.

c.Rinse in decreasing grades of alcohol: 100% > 90%>80%.

d. Keep under running water 15min and rehydrate.

2. Stain the slide with haematoxylin - 10 minutes.
3. Wash the slide in running tap water - 15minute.
4. Differentiate in acid alcohol.
5. Wash the slide in running tap water - 15minute.
6. Stain with eosin - 1 minutes.
7. Dehydrate, clear and mount.
8. The slides were than observed under microscope.

IV. IMMUNOHISTOCHEMICAL STAINING FOR TISSUE SAMPLE

The technique used was based on the labelled streptavidin biotin (LSAB) method. Endogenous peroxidase was blocked by first activating the section in 0.6 % H_2O_2. The specimen was then incubated with primary antibody followed by the sequential incubations with biotinylated link antibody and peroxidase labelled streptavidin staining was completed after incubation with substrate chromogen solution.

PROCEDURE

A. PARAFFIN EMBEDDED TISSUE

The tissues were fixed in 10 % formal saline for 24 hours. The tissues were then processed and embedded in paraffin.

B. ADHERENCE OF SECTIONS OF SLIDES

Polylysine – coated (Biogenex CA, USA) slides were used for the proper adherence of tissue section (other adhering agents which can be used are gelatin chrome, APES, Ainenopropyltriethoxy silane). Unstained section of 5 um thickness was cut using microtome and was transferred on polylysine coated slides from the paraffin blocks.

C. DEPARAFFINIZATION AND REHYDRATION

Sections were de-waxed thoroughly on slide warming table at 65 degree for half an hour.
Then sections were given two changes in xylene I, xylene II for 7 minutes each and then slides were allowed to dry.
Rinsed in alcohol for 3 minutes – two changes
The embedding medium must be completely removed. Any residual medium can cause increase in background staining and obscure specific staining.
Sections were kept in distilled water .

D. ANTIGEN RETRIEVAL

Antigen retrieval is the process by which antigenic epitopes, made unavailable because of fixation associated protein cross linking, are rendered accessible to antibodies for binding.
For this procedure buffer solution Tris- buffer was freshly prepared in which sodium citrate and citric acid was added with distilled water.

Preparation of Sodium Citrate Buffer: for 300ml

Buffer A: Citric Acid 2.10gm in 100ml distilled water
Buffer B: Sodium Citrate 2.950gm in 100ml distilled water
Buffer A + Buffer B
(9ml) + (41ml) = 50ml + 450ml distilled water = 500ml.
Slides were then placed in plastic coplin jars containing Tris buffer solution (PH-6) and irradiated in enzyme reteriver (microwave oven) (Biogenex CA, USA) at 96 degree for 10 minutes (two cycle)After heating the jar were removed from the oven and then slides were allowed to cool.Slides were then placed in the phosphate buffer saline (PBS) which is freshly prepared.

Phosphate buffer saline contains

Sodium chloride: 8.5gm
Di sodium hydrogen phosphate anhydrous (purified): 1.84g (Merck, India)
Sodium di- hydrogen phosphate (purified): 8.6gm in 1000ml of distilled water.
Here the slides are dipped in PBS solution for 5 minutes.

REDVET - Revista electrónica de Veterinaria - ISSN 1695-7504
Vol 25, No. 2 (2024)
http://www.veterinaria.org
Article Received: Revised: Accepted:

E. STAINING PROTOCOL

STEP 1: Excess buffer was wiped off.
Specimen is incubated with **PEROXIDASE BLOCK(Biogenex CA, USA)** for 15 minutes .
Then slides were again washed with PBS solution. As the PBS acts as aqueous medium.

STEP 2: POWER BLOCK (BIOGENEX CA, USA) is used almost covering the specimen on the slide for 10 minutes in wooden box .

STEP 3: PRIMARY ANTIBODY (BIOGENEX CA, USA)
Slides are blot dried and then sections were covered with optimally diluted primary antibody of CD1a (Biogenex CA, USA) incubated for 1 hour.
Here precautions must be taken to avoid dryness of the tissue.

STEP 4: SUPER ENHANCER (Biogenex CA, USA)
Incubated on the specimen for 20 minutes followed by rinse with PBS

STEP 5: **POLY HRP REAGENT (HORSERADISH PEROXIDASE) (BIOGENEX CA, USA)**
Excess buffer was wiped off.
Enough drop of Poly HRP reagent were applied to cover the specimen and incubated for 30 minutes at room temperature. Again wash in PBS solution.

STEP 6: SUBSTRATE CHROMOGEN SOLUTION
(BIOGENEX CA, USA)
Slides were wiped as before.
Enough of freshly prepared substrate chromogen solution was applied to cover the section and incubated at room temperature for 10 minutes.

STEP 7: COUNTERSTAIN
SECTIONS WERE COUNTERSTAINED WITH HEMATOXYLIN
DAB chromogen gives alcohol insoluble end product. Therefore alcohol based haematoxylin eg Harris Haematoxylin used.

STEP 8: MOUNTING
Stained sections were dehydrated, cleared and mounted in DPX (DistreneDebutyl – Pthalate Xylene)

INTERPRETATION OF STAINING
The positive control was examined for the presence of a coloredend product at the site of the target antigen (Dab chromogen brown end product). The presence of these colors was interpreted as a positive staining result indicating proper performance of kit reagents.The negative control was examined. The absence of specific staining in the negative control confirmed the specificity of primary antibody.LCs were identified in the epithelium by their intensely staining dendritic processes & generally suprabasal location. Criteria for LC identification :- only cells with a definable cell body & nucleus & at least one dendritic process were considered LCs.The average number of LCs were calculated & compared with the normal oral epithelium.

Statistical Methods:
Discrete statistical data was analysed by Chi square test & Independent Student t- test & LCs were counted by manual tagging on Leica Suite Image Analysis Software.
Grid Microscope was used to measure the depth of connective tissue fibrosis.
Number of positive cells are expressed as mean +/- standard deviation.

OBSERVATIONS AND RESULTS

30 patients with OSMF and 10 controls were selected for our study and were analysed for correlation of LC density in various grades of OSF epithelium with normal epithelium and depth of connective tissue fibrosis& degree of chronic inflammation in subepithelial connective tissue with help of detailed clinical examination, routine histopathological evaluation (H & E), and immunohistochemistry. All the findings were compiled and analysed for various comparative analyses using all the parameters with the help of Chi – square test and Student t- test.

All the observations were categorized in 5 groups as per aims and objectives

I.To study the clinical profile of oral Submucous fibrosis Patients.

II. Correlation of clinical groups according to Lai D.R *et al*. criteria with histopathological grade according to Rooban T. *et al*.

III. Correlationof no. of LCs in the epithelium with Histopathological stages/grades of OSMF.

IV. Correlation of LC density in OSF epithelium with depth of connective tissue fibrosis.

V.Correlation of LC density in OSF epithelium & degree of chronic inflammation in subepithelial connective tissue.

Correlation of H/P grade by H &E and clinical groups:

		CLINICAL GRADING					P-Value
		Group A	Group B	Group C	Group D	Total	
H/P grades	Very early	6	0	0	0	6	0.181
	Early	2	5	0	0	9	
	Moderately advanced	0	1	6	2	10	
	Advanced	0	1	3	1	5	
Total		8	7	8	7	30	

Profile distribution of subject group according to areca nut with tobacco& lime habit

	Areca Nut + Tobacco+Lime	
Frequency per day	**No of Patients**	**Percentage**
4	5	16.66
5	4	13.33
6	2	6.7
7	2	6.7
8	1	3.3
13	1	3.3

Correlation of No. of LCs in the epithelium with Histopathological stages/grades of OSMF.

1. The study group had 6(20%) subject's in group A with the LC density(37.00+/-7.69)with mean range (23-48),9(30%) subjects in group B with LC density(29.22+/-3.32) and mean range(28-38),10(33.33%) subjects in group C with LC density (23.2+/-8.30) and mean range(15-33) & 5(16.66%) subjects in group D with LC density (20.2+/-5.10) and mean range(9-26).Normal subjects10(33.3%) had LC density (54.90+/-11.91) with mean range (37-68)
2. Correlation Coefficient was estimated which gave value for H/P grade and number of LCs is0.000.This shows that there is strong positive relationship between H/P grade and no of LCs as compared to the normal mucosa.

Correlation of No. of LCs in the epithelium with histopathological stages/grades of OSMF

Oral epithelium	No.of subjects	LC density (cells/mm2 area)Mean +/-SD	Mean Range	P – value
Normal	10	54.50+/-11.91	37-68	0.000
OSF(very early) group A	6	37.00+/-7.69	33-48	
OSF(early) group B	9	29.22+/-3.32	28-38	
OSF(moderately dvanced) group C	10	23.2+/-8.30	15-33	
OSF(advanced) group D	5	19.2+/-5.10	9-26	

III.Correlation of LC density in OSF epithelium with depth of connective tissue fibrosis

1. Correlation Coefficient was estimated which gave value for LC density with depth of connective tissue fibrosis in OSF as 0.001 , which shows that there is strong positive relation between these two.

DISCUSSION

Oral submucous fibrosis (OSMF) predominantly affects Asiatic people & is characterized by inflammation & a progressive fibrosis of the juxta-epithelial & deeper connective tissue of oral mucosa. The major presenting complaint is a progressive inability to open the mouth because of accumulation of inelastic fibrous tissue in the subepithelial region of the oral mucosa, along with concomitant muscle degeneration. Recent epidemiological studies suggest the habit of betel nut chewing as a major etiologic factor. Histologically, OSMF is characterized by atrophy of the overlying epithelium with variable degrees of dysplastic change, & subepithelial fibrosis and hyalinization with a progressive loss of vascularity. Often there is variable chronic inflammatory cell infiltrate in the lamina propria & submucosa. OSMF is also regarded as a precancerous condition. It is regarded as possessing a high degree of malignant potential. Its precancerous nature was first mentioned by Paymaster in 1956, who observed the development of slowly growing squamous cell carcinoma in one-third of his patients. Since then more data have been presented by Pindborg to substantiate the hypothesis that submucous fibrosis is precancerous condition.

In the present study, LC density in OSMF epithelium was decreased compared with normal oral epithelium. The study group had normal subjects,10(33.3%) with LC value 54.50+/-11.91, 6(20%) subjects with the LC density values 37.00+/-7.69 in H/P grade 1, 9(30%) had LC density value 29.22+/-3.32 in H/P grade 2, 10(33.33%) had the value 23.2+/-8.30 in H/P grade 3and 5(16.66%) had a value 19.2+/-5.10 in H/P grade 4. Correlation Coefficient was estimated which gave value for H/P grade and LC density when compared with normal as 0.000 This shows that there is significant co-relationship between H/P grade and LC density.

If OSF is considered a precancerous condition, this result was consistent with that obtained by Mc Ardle & Muller. They demonstrated that LC density is significantly decreased in cervical condyloma, which may demonstrate premalignancy, especially when infected with HPV-16&18. The reduction of LC density in OSMF could reflect a defective local immune surveillance & may promote the development of oral cancer. The reason for decrease in the LC density in OSMF epithelium is reasonable to hypothesize that the recruitment of bone-marrow derived LCs from the circulation is decreased because fibrosis & hyalinization of subepithelial connective tissue & subsequent loss of vascularity usually develop as the stage of OSMF advances. Consistent with this hypothesis is that; tissue fibrosis – induced decrease in LC number has also been reported in a group of tongue squamous cell carcinoma.

Although the LC number in OSMF was significantly reduced as the stage advances as compared to the normal oral epithelium, this study did not appreciate much of a difference between the moderately advanced & advanced histologic stages. This result may be due to the fact that though there are histologic differences, no significant loss of vascularity & recruitment of LCs from the circulation is detectable. LC density is not noticeably decreased in the early stage (as compared to the mean ranges) of OSMF, but is markedly decreased in the late stage.

Diminished nutritional supply resulting from subepithelial connective tissue fibrosis might shorten the life span of LCs & thus decrease the number of LCs in the OSMF epithelium. Hence with the severity of OSMF(as observed in the H&E stained sections), the depth of connective tissue fibrosis is increased as a result there is decrease in the LC density ie ; there is significant correlation of LC density with the depth of connective tissue fibrosis.

There was no significant difference observed between the various histopathological parameters & the LC density.
Similarly, as the grade/stage of OSMF advances the inflammatory cell infiltrate is hardly seen. Number of blood vessels are dramatically small in subepithlial zone. Marked fibrosis with hyaline changes seen extending from subepithelial to superficial muscle layers. This was observed by **Utsunomiya H, Tilakratne WM, Oshiro K et al in 2005.** Hence, decrease in local immune surveillance causes difficulty in the recruitment of LCs from circulation. Hence our results show decrease in LC density when compared to the degree of chronic inflammation in subepithelial connective tissue(as observed in H &E stained sections) as severity of OSMF progresses.

Our results on LC numbers in OSMF(precancerous lesion) were similar to those of **Rich & Reade** who found significantly fewer LCs in tobacco-associated leukoplakia; **Anjali Narwal &SusmitaSaxena.** A statistically significant difference was noted in the presence of LCs between normal, early and advanced OSMF (independent student's t-test; $p < 0.001$) Similar findings were reported by **Chun-Pin Chiang, Chi-Yuan Kao, Bu-Yuan Liu, Jeng-Tzung Wang,1998.**

CONCLUSION

There is great deal of interest in how Dendritic Cells (DCs) might be exploited as a form of immunotherapy. DCs are being studied as adjuvants for vaccines or as a direct therapy to induce immunity against cancer. DCs loaded with tumor lysates, tumor antigen-derived peptides, MHC class I restricted peptides, or whole protein have all been shown to generate anti-cancer immune responses & activity, including in some cases the ability to induce complete regression of existing tumor.

Thus, there is a great desire to test these strategies & use tumor-antigen bearing DCs as a vaccine in humans.
Thus, the reduction of LC density in OSF epithelium, which may indicate a decrease in local immune surveillance, not only provides histologic evidence for its premalignant character but also has an effect of fanning the flame-on the epithelial carcinogenesis.Also, more studies need to be carried out in the future in order to clarify the exact relationships among areca nut, tobacco, LCs, & premalignant & malignant oral lesions.
